U.S. Pat. No. 4,908,948, issued Mar. 13, 1990, discloses a method of etching apertures in sheets of thermoplastic material which initially has a thickness greater than the etch depth of the apertures. The sheet is positioned between the upper and lower platens of a flat die with the upper platen having a smooth surface. The upper platen has a series of holes therein which are smaller in diameter than the apertures to be formed in the thermoplastic material and larger than the diameter of the apertures in the thermoplastic material. The holes in the upper platen are positioned such that they correspond in size and position with the apertures to be formed in the thermoplastic material. The thermoplastic material is forced between the upper platen and lower platen by means of a punch which is a smaller size than the diameter of the apertures. The upper platen and the punch are forced against each other at a linear or rectilinear force which presses the upper platen and the thermoplastic material between the upper platen and the lower platen. The surface of the lower platen has a series of recesses therein which correspond in diameter and position to the series of holes in the upper platen. The recesses in the lower platen are smaller than the diameter of the holes in the upper platen. The punch is forced against the upper platen and the thermoplastic material between the upper platen and the lower platen, causing the punch and the thermoplastic material between the upper platen and the lower platen to be forced between the upper platen and the lower platen. As the punch is being forced against the upper platen, the thermoplastic material is subjected to an axial pressure in a direction from the upper platen to the lower platen. The thermoplastic material is thus forced between the upper platen and the lower platen until the thermoplastic material forms a sheet between the upper platen and the lower platen. The sheet has a thickness equal to the height of the holes in the upper platen such that the thermoplastic material forms the sheet between the upper platen and the lower platen and fills the hole in the upper platen such that the sheet has a height greater than the diameter of the hole in the upper platen. As the punch is being forced against the upper platen and the thermoplastic material is
